AI Overview

[Learn more](#)

A botnet is a network of internet-connected devices that are infected with malware and controlled by an attacker. The term "botnet" is a combination of the words "robot" and "network".

Cybercriminals use Trojan viruses to infect computers and take control of them. The attacker, known as the "bot-herder", can then remotely manage the infected devices, or "bots", to perform malicious activities.

Botnets can be used for a variety of cyberattacks, including:

- Distributed denial-of-service (DDoS) attacks
- Telephony denial-of-service (TDoS) attacks
- Phishing campaigns
- Account takeover
- Stealing sensitive information
- Sending spam
- Click fraud attacks

Botnets can be difficult to detect because they use a small amount of resources from each device. For example, a botnet might piggyback onto a device's browser, increasing traffic in a way that's too small for the user to notice.

While some botnets can perform helpful tasks, like managing chatrooms, they can be dangerous when misused for malicious purposes.

Generative AI is experimental.

A botnet is a network of computers infected by malware that are under the control of a single attacking party, known as the "bot-herder." Each individual machine under the control of the bot-herder is known as a bot.

How to remove botnet malware

A botnet is a group of Internet-connected devices, each of which runs one or more bots. Botnets can be used to perform distributed denial-of-service attacks, steal data, send spam, and allow the attacker to access the device and its connection. The owner can control the botnet using command and control software. [Wikipedia >](#)
